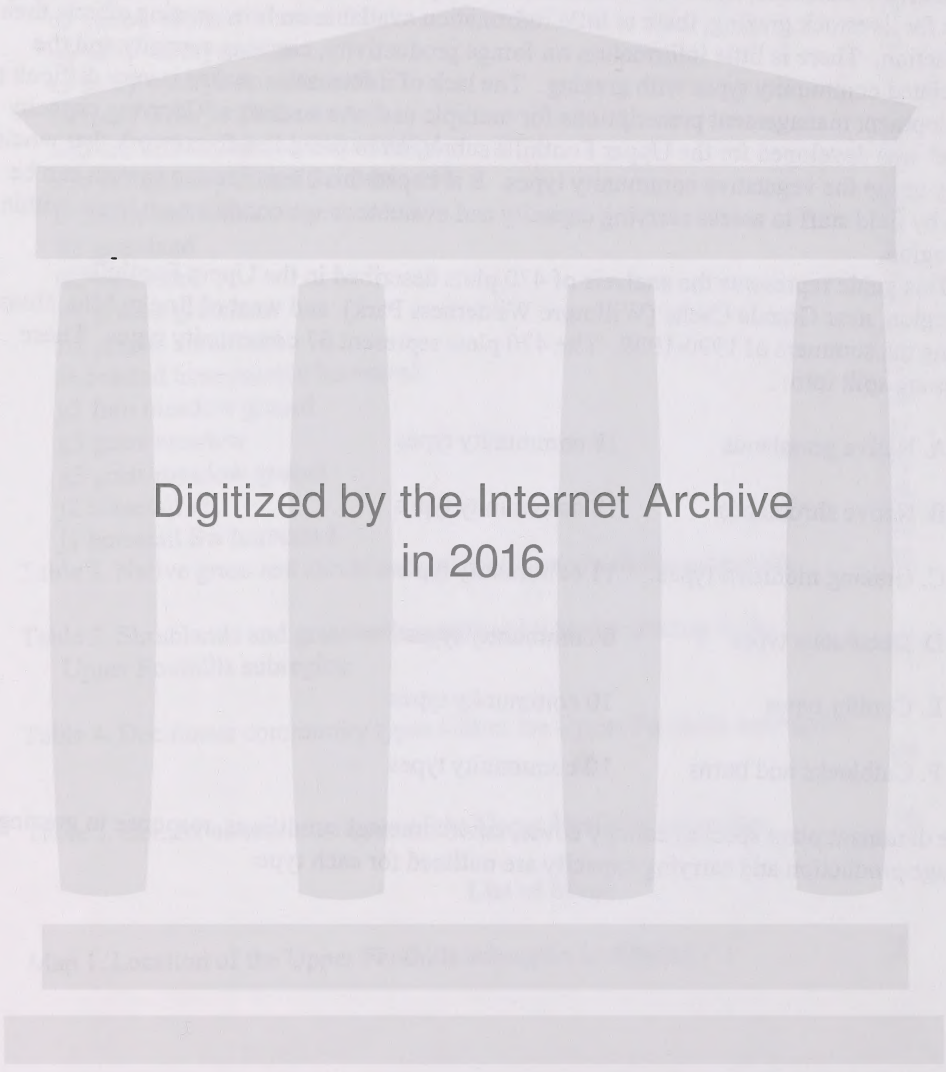
Abstract

The Upper Foothills subregion is found elevationally below the Subalpine and above the Lower Foothills subregions. It is dominated by closed canopied lodgepole pine forests. In the valley bottoms the shrub and grassland community types are a classic example of multiple use land, providing summer range for livestock, prime habitat for many species of wildlife, productive watersheds, and recreational areas. Despite the importance of these vegetation types for livestock grazing, there is little information available on how grazing affects their production. There is little information on forage productivity, carrying capacity and the associated community types with grazing. The lack of information makes it very difficult to development management prescriptions for multiple use. As a result a "Carrying capacity guide" was developed for the Upper Foothills subregion to provide a framework that would easily group the vegetative community types. It is hoped this classification system can be used by field staff to assess carrying capacity and evaluate range condition on lands within the region.

This guide represents the analysis of 470 plots described in the Upper Foothills subregion, near Grande Cache (Willmore Wilderness Park) and west of Rocky Mtn. House during the summers of 1990-1999. The 470 plots represent 67 community types. These types are split into:

A. Native grasslands	18 community types
B. Native shrublands	12 community types
C. Grazing modified types	11 community types
D. Deciduous types	6 community types
E. Conifer types	10 community types
F. Cutblocks and burns	10 community types

The dominant plant species, canopy cover, environmental conditions, response to grazing, forage production and carrying capacity are outlined for each type.



Introduction

The province of Alberta is covered by a broad spectrum of vegetation regions from prairie in the South, to alpine vegetation in the mountains and dense forests in the Central and Northern parts of the province. These broad vegetation regions have been classified into 6 natural regions and 20 subregions for the province (Dept. of Environmental Protection, 1994). Each of the regions consists of groups of plant communities which are influenced by environmental conditions and human impacts. Intensive management of these regions requires the ability to recoqnize the vegetative communities that have similar productivities and respond to disturbance in the same way. The increase in use of Alberta's northern forests has recently stimulated efforts to develop detailed classification systems. Some of these classification systems include Field guide to Forest ecosystems of West Central Alberta (Corns and Annas, 1986) and Field Guide to Ecosites of West-Central Alberta (Beckingham et al., 1996).

The vegetative communities in the province of Alberta are highly regarded by most resource managers for their ability to provide a wide variety of benefits. They are a classic example of multiple use land, providing summer range for livestock, prime habitat for many species of wildlife, productive watersheds and recreational areas. Despite the importance of these vegetation types for livestock grazing, there is little information available on how grazing affects their production. Specifically, there is little data on the levels of utilization which are detrimental to communities growth. There is also no data on forage productivity, carrying capacity and associated community types with grazing. Traditionally, these community types have been rated at 5 ac/AUM or 60 ac/head/year, but recent work has shown that productivity can vary significantly depending upon the ecological conditions of the site.

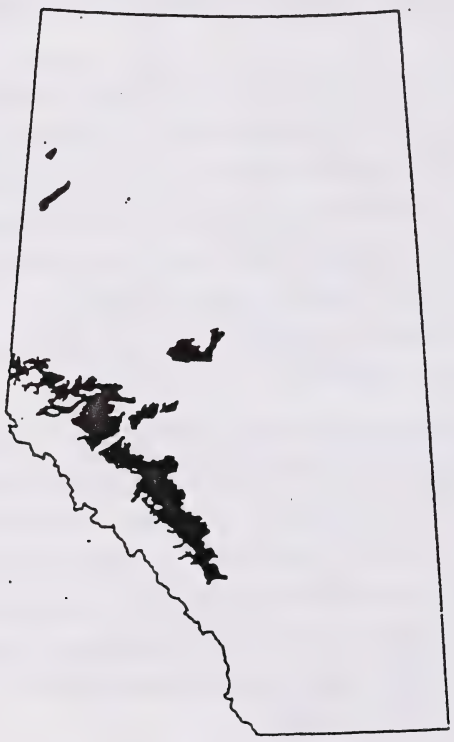
The purpose of this guide was to develop a framework that would easily group the vegetative community types in the Upper Foothills subregion of the province. The ultimate goal is a classification system that can be used by the field staff to assess carrying capacity and evaluate range condition on lands within the region. This guide supplements the work done by Beckingham et al. (1996) on the forested community types in the Upper foothills subregion. Their guide describes 65 community types on 13 ecosites. Beckingham's guide is a good description of the forested community types found within the subregion, but it does not include forage production values and carrying capacities. It also only provides a brief description of the native shrubland and grassland communities which are extensively utilized by livestock and wildlife in this subregion.

Climate of the Upper Foothills subregion

This subregion is found elevationally below the subalpine and above the Lower Foothills subregions. It ranges in elevation from 1200-1500m at lower latitudes and from 1000-1250 m at higher latitudes. It is dominated by closed canopy lodgepole pine forests with the potential climax species on reference sites being white spruce and black spruce. This

subregion can be distinguished from the Subalpine subregion by the lack of engelmann spruce and from the Lower Foothills by the lack of aspen.

This subregion has a boreal climate which is modified by the Rocky Mountains. The average annual precipitation is 538 mm with over half the precipitation recieved in the summer months (340 mm). The temperature averages 11.5 ^{0}C in the summer and -6.0 ^{0}C in the winter. These temperatures are milder and not nearly as extreme as the other subregions within the Boreal forest and Foothills natural regions.



Map 1. Location of Upper Foothills subregion in Alberta

Methods

A community type approach (Mueggler, 1988) to classification was chosen in preference to the habitat type approach (Daubenmire, 1952) or ecosystem association approach (Corns and Annas, 1986) because of the lack of understanding of the successional sequences of the communities. Community types are aggregates of similar plant communities based upon existing floristics regardless of successional status (Mueggler, 1988). Community types are what is actually seen in the field. After defining the community types, they then can be linked to the ecosystem associations developed by Corns and Annas (1986) and Beckingham (1994). In the mean time community types can be used as the basis for mapping and range management planning.

Initially, grazing dispositions were inventoried by forest region in order to develop management plans following the procedure outlined in the Rangeland Resource Information System (1991). Individual plots were initially classified within a forest region using cluster analysis (SAS) and ordination (DECORANA, Gauch, 1982). These types were described in individual carrying capacity guides for each forest. This led to differences in classification of the same types between forests, particularly for deciduous forest types. In an effort to standardize the community name and gain some understanding of each community types ecology, all plots sampled in each forest were reclassified. As the study progressed it became quite evident that there were differences in the productivity of the communities between ecoregions. As a result, it was decided to develop the classification within the ecoregion framework (Strong and Leggat, 1992). An ecoregion is a geographical area that has broad vegetation zones combined with climatic data (Strong and Anderson, 1980). As a result, the vegetation within each ecoregion is strongly influenced by the climatic conditions. Recently, the department has adapted the Natural and Subregions of Alberta classification system. This system incorporates the Natural regions and subregions classification used by Parks with the Ecoregions of Alberta classification used by Forestry, Lands and Wildlife. The Upper Foothills subregion and Upper Boreal Cordilleran ecoregion share the same boundary.

Sampling for this guide occurred within the Upper Foothills subregion . This guide outlines the classification of 439 plots described during the summers of 1990-2000 in the Southern and Northern East Slope Forest regions.

A plot consisted of a 10x10 m macroplot and ten randomly selected 1x1 m microplots to record the canopy cover of shrubs and ten nested 20x50 cm microplots to record the canopy cover of forbs and grass. The inventory followed the Range Survey Manual (1992) and uses the MF5 form. At each macroplot a 50x100 cm was clipped and separated into trees, shrubs, forbs and graminoids, oven dried and weighed. The recommended stocking rate is based on 25 percent of the total production for forested types and 50% total production for grass and shrubland types and the fact that one animal requires 455 kg of dry weight material for one month of grazing.

How to use the guide

First decide what category the community type is in. If it is in the **Native grass** and **Shrub category** it will not have tree cover and be found on steep south facing slopes or moist lowland areas adjacent to streams and rivers. The predominant species will be native grasses, willow and bog birch. The **Grazing modified** community types will resemble the native shrub and grassland community types, but will show signs of extensive grazing pressure. These community types will be dominated by grazing resistant species Kentucky bluegrass, clover and dandelion. A couple of moderately grazed community types with a predominant native species cover are also found in this category.

The **Deciduous category** will be plant communities dominated by deciduous tree species aspen and balsam poplar and the **Conifer category** will be plant communities dominated by white spruce, lodgepole pine or black spruce tree species.

In order to understand how the community types in this guide are related to the ecosites and ecosite phases outlined in "Ecosites of West-Central Alberta" (Beckingham et al., 1996), the community types in this guide are arranged by ecosite and ecosite phase (Table 1). **Ecosites** are defined as ecological units that develop under similar environmental influences (climate, moisture and nutrient regime). An **ecosite phase** is a subdivision of the ecosite based on the dominant species in the canopy. Table 1 is a reproduction of Figure 14 in the Ecosites of West-Central Alberta guide with the community types in this guide highlighted. For the most part the ecosites and ecosite phases are the same, particularly for the forested community types, but a number of new ecosites and ecosite phases had to be created for the grass and shrubland community types (Table 1). These included (ff)(mesic/rich) fescue-california oatgrass ecosite, and the (c5) yellow mtn avens, (c6) hairy wildrye grassland, (ff1)grassland, (ff2) shrubland, (g3) grass meadow and (j2) horsetail Pb ecosite phases. The "Grazing succession" and "Harvesting succession" categories (Table 1) outline the successional sequence the community types will undergo with increased grazing pressure or harvesting. A number of new ecosite phases were created for these categories. These included (c2) harvested Aw, (c4) harvested Sw, (e1) tall bilberry/arnica Pl-Sw harvested, (ff1) grazed grassland, (ff2) grazed shrubland, (f4)bracted honeysuckle Sw harvested, (g2) grazed forb meadow, (g3) grazed grass meadow and (j1) horsetail Sw harvested. All of the new ecosites and ecosite phases are summarized within this guide.

Results

The analysis of the 470 plots distinguished 67 community types. These types were split into 6 categories:

A.) Native grasslands	(18 types)
B.) Native shrublands	(12 types)
C.) Grazing modified types	(11 types)
D.) Deciduous types	(6 types)
E.) Conifer types	(10 types)
F.) Cutblock types	(10 types)

The dominant plant species, canopy cover, environmental conditions, forage production and carrying capacity are outlined for each community type.

Table 1. Ecosites, ecosite phases and plant community types for the Upper Foothills subregion (adapted from Beckingham et al., 1996) (Highlighted community types are described in this guide, non-highlighted communities are outlined in the guide Ecosites of West-Central Alberta)

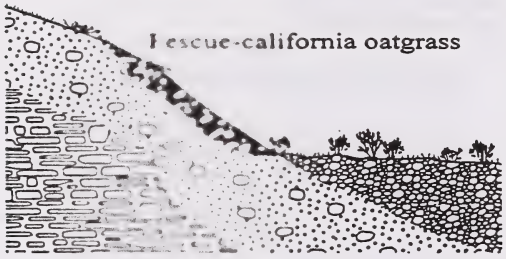
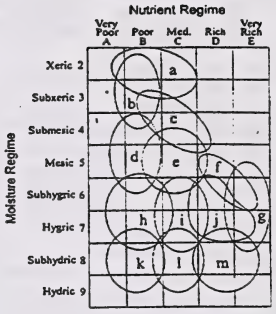
ff Fescue-California oatgrass grassland (n=70)

mesic/rich

GENERAL DESCRIPTION

This ecosite consists of open grasslands found in valley bottoms, adjacent to rivers and streams, and on south facing slopes. The ecosite tends to be meisc to submesic and occurs on loamy fluvial parent material where flooding and/or high water tables increase soil water content and replenish nutrients. The soils on these sites tend to have thick Ah horizons.





SUCCESSIONAL RELATIONSHIPS

Due to the nature of the site grasslands often remain the climax
vegetation on these sites. In the moister lower slope positions shrubs often dominate the site with succession to aspen and spruce. Disturbance regime, cold air drainage, and competion from a diverse cover of shrubs, forbs and grasses slow or inhibit the establishment of trees. If trees do become established, the rich loamy soils usually result in rapid growth.

UPPER FOOTHILLS SUBREGION

NATIVE GRASSLANDS AND SHRUBLANDS

Figure 1. Overview of native shrub and grassland complex in the Upper Foothills subregion

Native grass and shrublands

The native grass and shrubland community types (Table 2) are found in the valley bottoms, adjacent to streams and rivers, throughout the Upper Foothills subregion. Deep snow accumulations and cold air drainage prevent trees from growing in these valley bottoms (Daubenmire, 1978). Historically, these grass and shrublands burned frequently, further preventing tree encroachment.

The sequence of these community types along a moisture gradient from wet (UFA1 sedge meadows) to dry (UFA9 junegrass-sedge/ sage slopes) is outlined in Figure 3. The change in species composition from the wet sedge meadows to rough fescue and California oatgrass meadows may occur over a 3 foot elevational gradient.

The maintenance of these grassland community types is extremely fire dependent. The lack of fire allows bog birch and willow to expand, shading the modal grassland community types. Prolonged shading causes the understory composition to shift from a tufted hairgrass-rough fescue dominated understory to one dominated by slender wheatgrass and sedge (Figure 3). Under heavy shrub cover (pussy willow shrubland and willow-bog birch community types), there is little forb or grass understory. Increased shrub cover also causes a decline in forage productivity and reduces the accessibility for livestock.

Figure 2. Typical native shrub and grassland transition zone in Upper Foothills subregion

Table 2. Forage production and ecosite phases of the native grass and shrubland community types for the Upper Foothills subregion

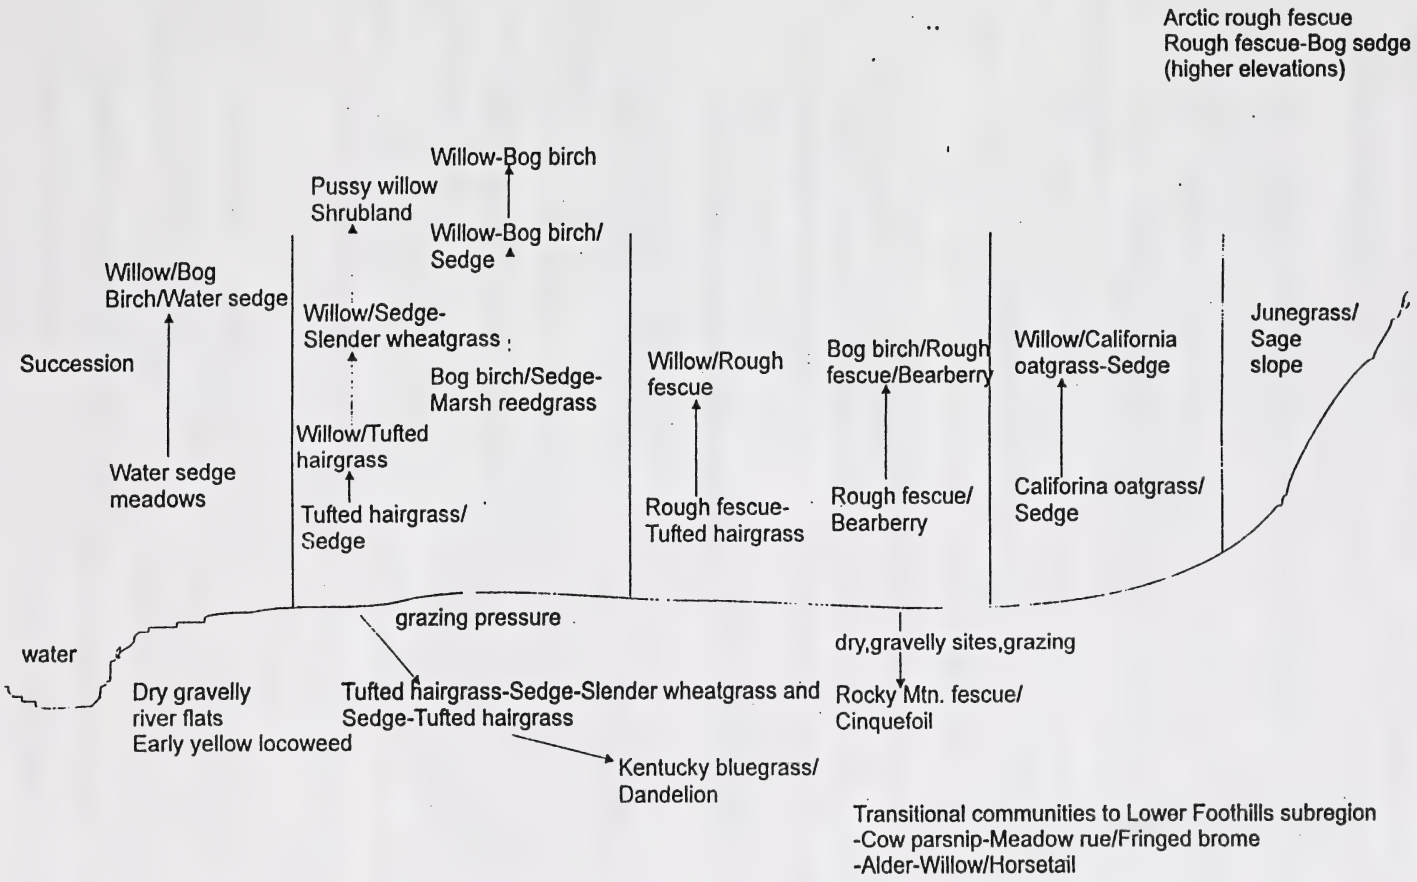

Figure 3. Layout of plant community types for native grass and shrublands in the landscape of the Upper Foothills subregion.

Key to Grassland Community Types (Grasslands dominated by native species)

1. Hydric, periodic flooding, depressional, dominated by sedges ..... UFA1 Water sedge meadows
   Drier, ungrazed or lightly grazed dominated by forbs or grass (rough fescue, tufted hairgrass) 2
2. Moist sites dominated by Forbs (Fireweed, Cow parnsip) 3
   Grass dominated(upland sedges, rough fescue, slender wheatgrass, hairy wildrye, tufted hairgrass) 4
3. Moist, lowland sites dominated by fireweed ..... UFA11 Fireweed/ Hairy wildrye (Forb meadow)
   Fine textured, silty soils, dominated by cow parsnip ..... UFA14 Cow parsnip-Meadow rue/ Fringed brome
4. Moist sites dominated by Tufted hairgrass with no rough fescue present at site, includes moderately grazed sites dominated by slender wheatgrass, Rocky Mtn. fescue and sedge species 5
   Drier sites dominated by rough fescue, hairy wildrye, california oatgrass, slender wheatgrass 6
5. Early successional sites with little slender wheatgrass, dominated by Tufted hairgrass ..... UFA3 Tufted hairgrass-Sedge
   Later successional or grazed tufted hairgrass or rough fescue meadows with abundant forbs, sedge, and slender wheatgrass 5a
5a Lightly grazed sites dominated by tufted hairgrass, Sedge and Slender wheatgrass.... ..... UFA4 Tufted hairgrass-Sedge-Slender wheatgrass
   Lightly to moderately grazed sites dominated by sedge, slender wheatgrass, Rocky Mtn. fescue or graceful cinquefoil 5b
5b Moderately to heavily grazed site dominated by Rocky Mtn. fescue or graceful cinquefoil..... ..... UFC2 Rocky Mtn. fescue/Graceful cinquefoil
   Lightly to moderately grazed site dominated by slender wheatgrass, sedge, low forb species or rough fescue 5c
5c Dry well drained sites with some rough fescue present..... UFC11Sedge-Slender wheatgrass-Rough fescue
   Moister sites, tufted hairgrass present..... UFC1 Slender wheatgrass-Sedge/Low forbs
6. Rough fescue dominated, higher elevation and moist sites 7
   Hairy wildrye, California oatgrass, slender wheatgrass, Idaho fescue, Parry oatgrass or Purple oatgrass dominated 12
7. Moist Alpine sites with globeflower, fleabane, monkshood, mountain heliotrope or drier sites with bog sedge .. 8
   Drier sites at lower elevations tufted hairgrass, hairy wildrye, bearberry or slender wheatgrass codominant 9
8. Dry well drained sites with bog sedge codominant ..... UFA12 Rough fescue-Bog sedge
   Moist Alpine sites with alpine forb species ..... UFA13 Alpine rough fescue
9. Moist sites codominated with Tufted hairgrass ..... UFA5 Rough fescue-Tufted hairgrass
   Drier well drained sites dominated by hairy wildrye, bearberry, ... 10
10. Lower, south facing slopes, well-developed soils hairy wildrye codominant .. UFA6 Rough fescue-Hairy wildrye
    Well drained sites with Bearberry present in understory 11
11. Shallow, well drained, gravelly soils, low nutrient ..... UFA7 Rough fescue/ Bearberry
    Ghost area California oatgrass dominated ..... UFA7a California oatgrass-Rough fescue/ Bearberry
12. California oatgrass dominated, well-drained soil, cold air drainage level areas in valley bottoms ..... UFA8 California oatgrass-Sedge
    Idaho fescue, Parry oatgrass, Hairy wildrye or Purple oatgrass dominated communities on south facing slopes or dry gravelly river beds 13
13. Low land moist meadows or dry gravelly river beds 15
    Steep south facing slopes..... 14
14. Steep, south facing slopes, shallow soils, drought tolerant species Junegrass, sage UFA9 Junegrass-Sedge/ Sage
    Hairy wildrye or Idaho fescue, Purple oatgrass, Parry oatgrass dominated sites 16
15. River bed, dry, gravelly, well drained sites ..... UFA10 Bearberry/ Slender wheatgrass
    Moist meadows dominated by drier sedge species ..... UFA2 Sedge-Slender wheatgrass/ Meadow rue
16. Hairy wildrye dominated 17
    Moister, south facing slopes in the Ghost area, Idaho fescue, Parry oatgrass, Purple oatgrass dominated grasslands 16a
16a Idaho fescue, Parry oatgrass dominated sites in the Ghost area..... UFA17 Idaho fescue-P.oatgrass-Sedge

Grazed sites dominated by Purple oatgrass and rough fescue.....UFC9 Purple oatgrass-Rough fescue
17. South facing slopes, at higher elevation.....UFA15 Hairy wildrye-Sedge
Grazed site, dominated by hairy wildrye, rough fescue present . . UFA16 Hairy wildrye-Rough fescue/Bearberry

Key to Grazing Modified Grassland and Shrubland Community Types (dominated by non-native species)

1. Native dominated 2
   Non-native dominated, creeping red fescue, Kentucky bluegrass, clover, dandelion . . . 7
2. Grass dominated (slender wheatgrass, rocky mtn. fescue, sedge, purple oatgrass, tufted hairgrass) 3
   Shrub dominated with K. bluegrass understory . . . . UFC10 Willow/ Kentucky bluegrass
3. Moist grassy meadows with rough fescue, tufted hairgrass still present on site 4
   Drier, well drained sites dominated by Rocky mtn. fescue
   . . . . . UFC2 Rocky mtn. Fescue/ Graceful cinquefoil

4 Slender wheatgrass, Sedge and purple oatgrass dominated community.....4a
Grazed tufted hairgrass communities(moister sites).....5

4a Slender wheatgrass and Sedge dominated.....UFC1 Slender wheatgrass-Sedge/Low forbs
Purple oatgrass dominates.....UFC9 Purple oatgrass-Rough fescue

3. Kentucky bluegrass present . . . . . UFC5 Tufted hairgrass-Kentucky bluegrass
   Kentucky bluegrass absent, recovering site . . . . . UFC6 Sedge-Tufted hairgrass

4. Kentucky bluegrass dominated 8
   Seeded sites with Creeping red fescue . . . . . UFC7 Creeping red fescue/ Clover

5. Heavily grazed sites with dandelion as co-dominant . . . . . .
   . . . . . UFC3 Kentucky bluegrass/ Dandelion
   Heavily grazed cow parsnip meadow, lower elevation sites, cow parsnip present in small amounts . . . . . UFC8 Kentucky bluegrass-Timothy/ Meadow rue

Key to Shrubland Community Types

1. Bog birch dominated 2
   Willow dominated 3

2. Dry, nutrient poor soils, with rough fescue ..... UFB5 Bog birch/ Rough fescue/ Bearberry
   Wet, poor drainage, no willow cover ..... UFB9 Bog birch/ Sedge-Marsh reedgrass

3. Poorly drained sites with water sedge in understory, or shrublands with little understory ... 4
   Drier well drained sites with slender wheatgrass, hairy wildrye, rough fescue, tufted hairgrass found in the understory 7

4. Poor drainage, very wet sites ..... UFB1 Willow-Bog birch/ Water sedge
   Shrub dominated sites with little understory willow and bog birch dominated 5

5. Tall willow or alder dominated 6
   Short willow, imperfectly drained sites little understory ..... UFB11 Willow-Bog birch

6. Occurring along water bodies ..... UFB7 Pussy willow shrubland
   Moist, nutrient rich seepage sites with alder and willow ..... UFB12 Alder-Willow/ Horsetail

7. Well drained sites with Hairy wildrye dominating the understory, typical of well drained valley bottomland sites ..... UFB8 Willow/ Hairy wildrye-Sedge
   Recently invaded grasslands with rough fescue, tufted hairgrass or california oatgrass, slender wheatgrass or graceful sedge 8

8. California oatgrass dominated ..... UFB6 Willow/ California oatgrass-Sedge
   Rough fescue or tufted hairgrass present in understory 9

9. Rough fescue dominated ..... UFB4 Willow/ Rough fescue
   Tufted hairgrass, graceful sedge or slender wheatgrass dominated 10

10. Tufted hairgrass dominated ..... UFB3 Willow/ Tufted hairgrass
    Sedge or Slender wheatgrass dominated understory.....11
11. Sedge dominated ..... UFB10 Willow-Bog birch/ Sedge
    Slender wheatgrass dominated ..... UFB2 Willow/ Slender wheatgrass-Sedge

UFA1. Water-Beaked sedge meadows

(Carex aquatilis-Carex rostrata)

n=14 Wet conditions and periodic flooding result in the formation of water sedge meadows. Bog birch and willow will invade into the drier edges of these meadows to form the willow-bog birch/ water sedge community type (UFB1).

These community types are quite productive, producing nearly 2000 kg/ha of forage, but the high water table in the spring and summer when these meadows are most palatable limits livestock use. A study in the Yukon found that crude protein on these meadows declined from a high of 10% in May to less than 5% in September (Bailey et al., 1992). As a result, these meadows would be rated as secondary or non-use range.

SUGGESTED GRAZING CAPACITY
NON-USE

UFA2. Sedge-Slender wheatgrass/ Meadow rue

(Carex spp.-Agropyron trachycaulum/ Thalictrum venulosum)

n=3 These sites are dominated by three sedge species that are adapted to moist conditions: *C. praticola, C. praegracilis* and *C. prairea*. The presence of small amounts of tufted hairgrass and rough fescue indicates that these sites may represent a phase of the rough fescue-tufted hairgrass plant community (UFA5). Past heavy grazing pressure may have shifted the plant community to one dominated by sedge species or these sites could be too wet for tufted hairgrass and rough fescue growth.

The forage productivity on this community type is good. In comparison with the water sedge meadows (UFA1), these sites remain drier throughout the growing season and this allows easy access for livestock. This community would be rated as primary range.

UFA3. Tufted hairgrass-Sedge

(Deschampsia cespitosa-Carex praegracilis)

n=34 This community is located on moist sites that are better drained and slightly drier than the pure sedge meadows (UFA1). Willoughby (1992) and Willoughby (1999), found that tufted hairgrass is a common plant species on these lowland sites throughout the Upper Foothills and Lower Subalpine subregions. At lower elevations, this species appears to be replaced by marsh reedgrass. When this community type is protected from grazing for 25-30 years, willow and bog birch expand (willow/ tufted hairgrass (UFB3)) and tufted hairgrass and sedge decline (Willoughby, 1992). The decline in graminoid cover also results in a decline in available forage production from 2200 to 1800 kg/ha. Continuous heavy grazing pressure causes hairgrass to decline and the site will be invaded by Kentucky bluegrass and dandelion.

Bork (1994), found this community type. to be the most productive type described in Willmore wilderness park. Forage production averages over 2000 kg/ha and can vary from 800-3300 kg/ha. This community type would be rated as primary range.

UFA4. Tufted hairgrass-Sedge-Slender wheatgrass

(Deschampsia cespitosa-Carex spp.-Agropyron trachycaulum)

n=8 This community type may be transitional between the willow dominated community types and the tufted hairgrass dominated grasslands. Two of the sites described in this community are represented by the inside, ungrazed transect at two rangeland reference area sites. Protection from grazing for 25-35 years appears to allow willow to expand and there is a shift away from a tufted hairgrass dominated community type to a type that is dominated by slender wheatgrass, sedge and tall forb species. Continued protection from grazing and fire will likely lead to a community dominated by willow and bog birch with little understory of forbs and grass.

UFA5. Rough fescue-Tufted hairgrass

(Festuca scabrella-Deschampsia cespitosa)

n=5 This community type is located up slope from the tufted hairgrass-sedge community type (UFA3) on drier, better drained soils. The drier soil conditions limit the amount of forage being produced. There was 300 kg/ha less forage produced in the rough fescue-tufted hairgrass community type compared to the tufted hairgrass-sedge community type (UFA3).

In the absence of fire and grazing, this community type will become dominated by willow and bog birch (willow/ rough fescue community type (UFB4)). Heavy grazing pressure also decreases the cover of rough fescue and tufted hairgrass and allows Kentucky bluegrass and dandelion to increase (Willoughby, 1992). The dominant plant species on this community are highly palatable and the sites are easily accessible to livestock. Consequently, this community would be rated as primary range.

UFA6. Rough fescue-Hairy wildrye

(Festuca scabrella-Elymus innovatus)

n=18 These grasslands are located on lower, south facing slopes. They represent the transition zone from the dry junegrass-sedge/ sage (UFA9) dominated south facing slopes to the moist rough fescue and tufted hairgrass dominated community types (UFA5). Grazing pressure causes a shift away from a rough fescue, hairy wildrye dominated community (UFA6) to a sedge, Kentucky bluegrass dominated community (UFC4) (Willoughby, 1992). These grasslands are fairly moist and have well developed soils which makes them very productive. This community type would be rated as primary range.

This community type is very similar to the rough fescue dominated communities described in the Ya Ha Tinda, west of Sundre (Willoughby et al. 2001)

UFA7. Rough fescue/ Bearberry

(Festuca scabrella/ Arctostaphylos uva-ursi)

n=4 This community type was described in the Upper Clearwater Forest Land Use Zone and is similar to the bog birch/ rough fescue/ bearberry community type but lacks the cover of bog birch. Willoughby (2001) felt that bog birch indicated sites with deeper snow accumulations. This community occupies sites that have shallow, well-drained, and gravelly soils and there maybe little snow cover which does not favour the growth of bog birch. This community is moderately productive but because of the poor soil conditions, precautions must be taken to prevent overutilization

UFA7a. California oatgrass-Rough fescue/ Bearberry

(Danthonia californica-Festuca scabrella/ Arctostaphylos uva-ursi)

n=2 This community type was described in the Ghost area west of Calgary. It appears to represent a transitional grassland between the Montane and Upper Foothills subregions. This community also appears to be transitional between the California oatgrass dominated grasslands (UFA8) and the previously described Rough fescue/Bearberry dominated community. This community is located on steep, south facing slopes and small hillcrests with well-drained subxeric soils. The dry site conditions limit the amount of forage available for domestic livestock and the steep slopes restrict livestock access. Consequently, this community type should be rated non-use.

ENVIRONMENTAL VARIABLES

UFA8. California oatgrass-Sedge

(Danthonia californica-Carex praegracilis)

n=9 Dry, gravelly or stony soils support this moderately productive grassland that is dominated by California oatgrass. Small pockets of this community type occur throughout the Upper Foothills subregion. In the Yukon, these small meadows were found to form in depressions which appeared to act as pronounced frost pockets (Bailey et al., 1992). In the Subalpine subregion, these California oatgrass dominated grasslands are often associated with bog sedge (Willoughby 1999). The cold air drainage and poor nutrient quality of the soil limits the forage productivity of these sites.

ENVIRONMENTAL VARIABLES

UFA9. Junegrass-Sedge/ Sage

(Koeleria macrantha-Carex spp./ Artemisia frigida)

n=4 This community type occurs on steep, south facing slopes with shallow soils overlying sandstone bedrock. The majority of the vegetation is composed of the drought tolerant species: sage, bearberry and junegrass. The inaccessibility and fragile nature of the soils make this community type unsuitable for grazing.

This community type is very similar to the blunt sedge-rocky mtn. fescue/ bearberry community described by Willoughby (1999) and the junegrass-hairy wildrye-brome community described by Corns and Achuff (1982) on steep south-facing slopes in the Subalpine subregion.

ENVIRONMENTAL VARIABLES

UFA11. Fireweed/ Hairy wildrye (Forb meadow)

(Epilobium angustifolium/ Elymus innovatus)

n=3 This community type is found on moist lowland sites adjacent to the lodgepole pine and white spruce dominated forests. It represents the transition from the willow and grass dominated riparian areas to the conifer dominated forests. In the absence of disturbance (fire) it appears that succession of conifers into the grassy meadows shifts the species dominance away from a predominantly graminoid cover to one dominated by forbs such as fireweed, Lindley's aster and palmate leaved coltsfoot. There is also a shift in grass cover away from tufted hairgrass, rough fescue and sedge species to more shade tolerant grass species such as purple oatgrass and hairy wildrye. Periodic burning of this site is required to limit tree and shrub expansion.

This community type is very productive and easily accessible to livestock. It would be rated as primary range.

UFA13. Arctic rough fescue

(Festuca altaica)

n=2 This community was described at higher elevations in Willmore Wilderness Park. Bork (1994), described this community type on alpine and subalpine slopes where climate and soil conditions are still suitable for fescue to dominate in the stand. The community has a subhygric moisture regime and is moderately well drained. Forb species such as globeflower, fleabane, monkshood, and mountain heliotrope are all characteristic of these high elevation meadows.

This community is much wetter than the rough fescue-bog sedge community (UFA12) previously described and is similar to the forb meadows community type described by Willoughby (1999) in the Subalpine subregion.

UFA14. Cow parsnip-Veiny meadow rue/ Fringed brome

(Heracleum lanatum-Thalictrum venulosum/ Bromus ciliatus)

n=1 This community type is transitional between the Lower Foothills and Upper Foothills subregions. It was described on fine textured, silty soils adjacent to the Baptiste river west of Rocky Mountain House. Grazed stands of this community type were also described in the Solomon valley, west of Hinton. Increased grazing pressure generally allows timothy, Kentucky bluegrass and dandelion to increase with a corresponding drop in the cover of cow parsnip, meadow rue and the native grasses and sedges. The high moisture and nutrient regime of this site makes it extremely productive, and once it has been invaded by agronomic species it is highly palatable for domestic livestock. It is difficult to find representative stands of this community type that have not been grazed.

UFA15. Hairy wildrye-Sedge

(Elymus innovatus-Carex spp.)

n=1 This community type was described on south facing slopes along Wilson Creek in the Upper Foothills subregion. Corns and Achuff (1982) described similar community types in the subalpine of Banff and Jasper National Parks. These included the shrubby cinquefoil/ hairy wildrye and hairy wildrye/ bearberry-juniper community types. Both of these community types were associated with steep south facing slopes. The presence of this community type may indicate the transition to the Subalpine subregion.

This community type does not produce a large amount of forage because of the dry site conditions and poor nutrient content of the soil, but the lack of open areas for livestock grazing in this subregion makes these grassland sites attractive to livestock.

UFA16. Hairy wildrye-Rough fescue/ Bearberry

(Elymus innovatus-Festuca scabrella/ Arctostaphylos uva-ursi)

n=1 This community was described in the Ghost area west of Calgary on a well drained, level valley floor. It appears to represent a grazed rough fescue, bearberry or hairy wildrye dominated community. Willoughby (2000) found that heavy grazing on the rough fescue dominated grasslands often leads to a community that is dominated by sedge and hairy wildrye. Protection from grazing or a reduction in stocking rate allows this community type to recover back to a rough fescue dominated community. The time frame for complete recovery takes 20 years (Willoughby 2000)

UFA17. Idaho fescue-Parry oatgrass-Sedge

(Festuca idahoensis-Danthonia parryi-Carex spp.)

n=2 This community type was described in the Ghost area west of Calgary. This area represents a transition between the Montane and Upper Foothills subregions. This community type is very similar to moderately and heavily grazed rough fescue dominated communities in the Montane subregion. Both Idaho fescue and Parry oatgrass are more characteristic of the Montane subregion and increase with increased grazing pressure. Protection from grazing will often allow this community type to recover back to a Rough fescue-Parry oatgrass dominated community type.

UFB1. Willow-Bog birch/ Water sedge

(Salix spp.-Betula glandulosa/ Carex aquatilis)

n=45 This shrub community appears in areas with very poor drainage. It is found in association with the wetter water sedge meadows (UFA1). These sites are fairly productive but are difficult to graze due to the moist ground conditions and heavy shrub cover which reduces access and mobility in the area. Increased flooding and prolonged water logging may result in the disappearance of willow and a transition to a water sedge meadow.

UFB2. Willow/ Slender wheatgrass-Sedge

(Salix spp./ Agropyron trachycaulum-Carex spp.)

n=4 This community type is very similar to the tufted hairgrass-sedge-slender wheatgrass c.t. (UFA4) previously described. Both community types appear to represent the various stages of succession onto tufted hairgrass meadows. When these communities are protected from disturbance (fire and grazing), willow and bog birch expand and tufted hairgrass declines. Willow growth also appears to favour the growth of tall forbs (veiny meadow rue, fireweed, aster) and slender wheatgrass. Fire has played a dominant role in controlling brush encroachment in the past and continued protection will allow continued shrub expansion, resulting in a decline in forage production.

UFB3. Willow/ Tufted hairgrass

(Salix barclayi/ Deschampsia cespitosa)

n=16 This community type is found in association with the tufted hairgrass-sedge c.t. (UFA3). Willow encroachment into a tufted hairgrass meadow eventually results in this community type. Historically, fire has played an important role in the maintenance of the grassland community types in this subregion. Continued fire suppression will eventually allow willow and bog birch to invade many of these grassy meadows.

The encroachment of willow onto the tufted hairgrass-sedge c.t. causes a decline in forage production from 2200 kg/ha to 1200 kg/ha for grass and forb production. Continued protection of this community type from disturbance will most likely lead to the development of a community type similar to the willow/ slender wheatgrass (UFB2) and then to the pussy willow shrubland (UFB7). The latter community has a high cover of willow (71%) and very little forage for domestic livestock.

UFB4. Willow/ Rough fescue

(Salix barclayi/ Festuca scabrella)

n=2 This community type was described by Bork (1994) in Willmore Wilderness Park. Bork felt this community type originated from recent shrub encroachment onto rough fescue grasslands. Continued shrub expansion will result in decreasing forage productivity. Bork also felt that fescue will be replaced by wheatgrass and sedge plant species. These plants being better adapted to shading and competition from adjacent shrubs.

UFB5. Bog birch/ Rough fescue/ Bearberry

(Betula glandulosa/ Festuca scabrella/ Arctostaphylos uva-ursi)

n=19 This community type is very similar to the rough fescue-bearberry (UFA7) type previously described, but it is successionally more advanced. The soils on this community type are gravelly, drier and have a poorer nutrient regime than the other rough fescue and tufted hairgrass dominated community types. The lack of fire on this community type has allowed the shrub cover to expand, reducing forage productivity for wildlife and domestic livestock. In one study, burning a bog birch/ rough fescue/ bearberry community type twice in 3 year intervals controlled birch growth and increased total forage production by over 40% compared to the unburned control (Bork, 1990).

UFB6. Willow/ California oatgrass-Sedge

(Salix barclayi/ Danthonia californica-Carex spp.)

n=4 This community type likely develops from willow encroachment onto an oatgrass dominated meadow. The oatgrass meadows are found on dry, gravelly soils. These meadows may also form in frost pockets. The spread of willow is likely caused by the lack of natural disturbance, such as fire. The cover of willow on this community type is fairly extensive. This will restrict access of domestic livestock. This community type would be rated as secondary range.

UFB7. Pussy willow shrubland

(Salix discolor)

n=2 This community type is common along riparian areas, swamps and fringes of marshes and lakes. It appears to be successionally more advanced than the other willow dominated community types described in this guide. As the willow cover expands over time it shades the understory vegetation resulting in a loss of forage productivity. This community type produces only 200 kg/ha and is generally inaccessible to domestic livestock. This community type should be rated as non-use.

UFB8. Willow/ Hairy wildrye-Sedge

(Salix barclayi/ Elymus innovatus-Carex spp.)

n=2 This plant community represents a rough fescue-hairy wildrye community type (UFA6) that has continued to undergo succession in the absence of fire and grazing. Willow cover has increased, shading the growth of grasses (rough fescue) and allowing tall-growing forbs (fireweed, aster, veiny meadow rue) to increase. Continued protection from disturbance will allow succession to shrub and eventually tree species. The understorey vegetation will be increasingly shaded and forage production will continue to decrease.

UFB9. Bog birch/ Sedge-Marsh reedgrass

(Betula glandulosa/ Carex spp.-Calamagrostis canadensis)

n=1 This community type occupies valley drainages on soils that are saturated with water for part of the growing season. This type is very similar to the willow-bog birch/ sedge (UFB1) c.t, but lacks the willow cover. It is not clear why there is no willow cover on this type. It is possible that bog birch is better adapted to growing on poor nutrient soils. The presence of marsh reedgrass may indicate the transition from the Lower Foothills to Upper Foothills subregion. Willoughby (1992), observed that marsh reedgrass was more abundant on these lowland sites at lower elevations.

The thick cover of bog birch and very wet conditions restrict access to domestic livestock. Consequently, this community type would be rated as secondary or non-use range.

UFB10. Willow-Bog birch/ Sedge

(Salix barclayi-Betula glandulosa/ Carex spp.)

n=12 This type is very similar to the willow-bog birch/ water sedge community type (UFB1), but the soils are drier and better drained. The drier soil conditions favour the growth of graceful sedge over water sedge.

This community type has a thick cover of bog birch and willow which restricts livestock access to the forage. This community type would be rated as secondary or non-use range.

UFB11. Willow-Bog birch

(Salix barclayi-Betula glandulosa)

n=11 This community type is very similar to the willow-bog birch/ sedge c.t. (UFB1), but is successionally more advanced. The lack of fire has allowed continued expansion of the shrub cover. This has restricted access to livestock and lowered forage productivity. This community type would be rated as non-use for domestic livestock.

UFB12. Willow-Alder/ Horsetail

(Salix bebbiana-Alnus tenuifolia/ Equisetum arvense)

n=1 This community type was described on the boundary between the Upper and Lower foothills subregions in the Solomon valley northwest of Hinton. It is very similar to the to the willow-alder/ shield fern-wild sarsaparilla community described by Lane et al (2000) in the Saddle Hills north of Grande Prairie. This community tends to occupy moist nutrient rich seepage areas which favour the growth of willow, horsetail and fern species. The high cover of willow and alder limits productivity of forbs and grass. It also limits access to domestic livestock. As a result this community type would be rated as non-use.

UPPER FOOTHILLS SUBREGION

SHRUBLANDS AND GRASSLANDS MODIFIED BY GRAZING

Figure 4. Heavily grazed Kentucky bluegrass/Dandelion community type

Grazing modified community types

The grazing modified community types in the Upper Foothills subregion are outlined in Table 3. There are a few grasslands that exhibit signs of historic heavy grazing. These sites are predominantly covered by Kentucky bluegrass, timothy, dandelion and clover plant species (UFC3. Kentucky bluegrass-sedge/ dandelion and UFC4. Kentucky bluegrass/ dandelion and UFC8. Kentucky bluegrass-Timothy/Veiny meadow rue). Under long-term moderate grazing pressure or heavy grazing over a couple of years, there is a general decline in rough fescue and tufted hairgrass and an increase in sedge and slender wheatgrass (UFC1 Slender wheatgrass-sedge/ strawberry and UFC11.Sedge-Slender wheatgrass-Rough fescue). When these plant communities are protected from grazing, they appear to succeed back to the original communities dominated by rough fescue and tufted hairgrass. However, when Kentucky bluegrass becomes established, the community appears to revert to a rough fescue or tufted hairgrass-Kentucky bluegrass-dominated plant community (UFC5. Tufted hairgrass-Kentucky bluegrass) when protected from grazing.

The climax range condition model suggests that vegetation development will be directional, predictable and revert to the original vegetation when protected from grazing, but once Kentucky bluegrass has established, bluegrass appears to compete with rough fescue and tufted hairgrass for co-dominance. These Kentucky bluegrass communities move toward a different community rather than back to the original vegetation when protected from livestock disturbance.

The Rocky Mtn. fescue/ graceful cinquefoil community (UFC2) appears to be a moderately to heavily grazed California oatgrass community type. The dry, gravelly conditions on this site do not appear to favour the growth of Kentucky bluegrass under heavy grazing conditions.

The Creeping red fescue/ Clover (UFC7) community type represents seeded pastures and pipelines within the Upper Foothills subregion. This community type usually occurs at lower elevations, adjacent to farms and ranches where extensive modification of the native grass and shrublands have taken place.

The Purple oatgrass-Rough fescue (UFC9) community type was described in the Ghost area west of Calgary. It appears to represent a rough fescue, hairy wildrye dominated grassland that has undergone heavy grazing pressure. Willoughby (2000) has described purple oatgrass communities on saline soils in the Dry Mixedwood subregion. It is possible that this community type maybe associated with a saline seepage area which favours the growth of purple oatgrass.

Table 3. Shrublands and grasslands modified by heavy grazing pressure in the Upper foothills subregion

UFC1. Slender wheatgrass-Sedge/ Low forbs

(Agropyron trachycaulum-Carex spp./ Fragaria virginiana)

n=10 This community type appears to arise from grazing a modal fescue-tufted hairgrass community (UFA5). Moderate to heavy grazing causes fescue and hairgrass, both decreasers, to decline in the stand. This community is very common in the valley bottoms in areas that are heavily utilized. While still quite productive, these sites have lost two of the most advantageous species. Only a reduction in grazing pressure will once again allow fescue and tufted hairgrass to become prevalent in the stand.

UFC2. Rocky Mountain fescue/ Graceful cinquefoil

(Festuca brachyphylla/ Potentilla gracilis)

n=1 This community type was described on a gravelly, well drained site adjacent to Fall creek. It appears that this site was once a California oatgrass-sedge community type (UFA8), but heavy grazing pressure has shifted the community to one dominated by unpalatable low growing graminoids and forbs (Rocky mountain fescue, sedge, yarrow, graceful cinquefoil, pussy toes). The dry site conditions and poor nutrient conditions do not favour the growth of Kentucky bluegrass. This community type would benefit from a deferred rotational grazing system, where the community is rested every other year.

UFC3. Kentucky bluegrass/ Clover-Dandelion

(Poa pratensis/ Trifolium spp.-Taraxacum officinale)

n=23 This community type develops when the modal tufted hairgrass-sedge dominated communities (UFA3, UFA4) are grazed heavily for prolonged periods of time. Willoughby (1992), felt these grasslands exhibited signs of historic heavy grazing pressure. He felt that under long-term moderate grazing or heavy grazing over a couple of years, rough fescue and tufted hairgrass decline and sedge, slender wheatgrass, and low growing forbs increase. When these plant communities are protected from grazing, they appear to succeed back to the original communities dominated by rough fescue and tufted hairgrass. However, when Kentucky bluegrass becomes established the community appears to revert to a rough fescue or tufted hairgrass-Kentucky bluegrass dominated plant community (UFC5).

These community types are highly productive for domestic livestock during the growing season, but the poor quality of Kentucky bluegrass, particularly in the dormant season, limits the use of these community types for wildlife.

UFC4. Kentucky bluegrass-Sedge/ Dandelion

(Poa pratensis-Carex spp./ Taraxacum officinale)

n=25 This community type is similar to the Kentucky bluegrass/ clover-dandelion community type (UFC3), but it has not been grazed as heavily. There is still an abundance of native plant species such as veiny meadow rue, slender wheatgrass, tufted hairgrass and sedge, but there has been an increase in grazing resistant species, such as Kentucky bluegrass, dandelion and clover. If this community type is protected from grazing it will probably revert back to a tufted hairgrass-Kentucky bluegrass dominated type (UFC5) (Willoughby, 1992). Kentucky bluegrass, once established, appears to be a successful competitor.

These Kentucky bluegrass dominated community types are very productive, but they have lost two of the most advantageous species (tufted hairgrass and rough fescue). The forage quality of these native species is much better, particularly in the dormant season.

UFC5. Tufted hairgrass-Kentucky bluegrass

(Deschampsia cespitosa-Poa pratensis)

n=4 This community type is similar to the other Kentucky bluegrass dominated community types, but grazing pressure has been lighter or it was heavy and then became more moderate because of reduced stocking rates or rotational grazing. Willoughby (1992), found that tufted hairgrass could compete with Kentucky bluegrass in the absence of grazing, but it appears that once Kentucky bluegrass is established it remains to form a stable community type.

UFC6. Sedge-Tufted hairgrass

(Carex spp.-Deschampsia cespitosa)

n=13 This community type was described at Harrison Flats in the Upper Clearwater River valley. It appears to represent a tufted hairgrass-sedge community that was heavily grazed in the past and now is rested and only lightly utilized. It appears that the heavy grazing pressure was not prolonged enough to allow Kentucky bluegrass invasion. It is also possible that Kentucky bluegrass is not predominant on this site because of lack of seed source in these isolated areas. It is likely, with continued protection from grazing, that this community type will succeed back to a modal tufted hairgrass-sedge dominated community type.

UFC7. Creeping red fescue-Clover

(Festuca rubra-Trifolium spp.)

n=23 This community type was described at lower elevations, adjacent to farms and ranches in the Upper Foothills subregion. This community represents native communities that have been disturbed and planted to creeping red fescue. These include pipelines, roadsides and cultivated pastures. Lane et al. (2000), felt this community type developed when a site which was seeded to creeping red fescue-timothy-clover and received low levels of use. Creeping red fescue spreads throughout the site by creeping rhizomes and chokes out the timothy by forming a dense matt of litter. This community type is normally considered to be in good or excellent condition.

UFC8. Kentucky bluegrass-Timothy/ Meadow rue

(Poa pratensis-Phleum pratense/ Thalictrum venulosum)

n=4 This community type represents the grazed and disturbed community of the cow parsnip-meadow rue/ fringed brome community (UFA14). The high productivity and open nature of this community make it extremely attractive to domestic livestock. Heavy to moderate grazing pressure causes cow parsnip, veiny meadow rue and fringed brome to decrease and allows Kentucky bluegrass, timothy and dandelion to increase.

UFC9. Purple oatgrass-Rough fescue

(Schizachne purpurascens -Festuca scabrella)

n=1 This community type was described in the Ghost area west of Calgary. It appears to represent a rough fescue, hairy wildrye dominated grassland that has undergone heavy grazing pressure. Willoughby (1995) has found that purple oatgrass will increase with increased grazing pressure on nutrient poor soils in the Lower Foothills subregion. Willoughby (2000) also described a purple oatgrass-california oatgrass dominated community type on saline soils in the Dry Mixedwood subregion. It is possible that this community type maybe associated with a saline seepage area which favours the growth of purple oatgrass.

This community type is fairly productive, but the majority of the production is coming from purple oatgrass which is only moderately palatable to livestock. This community type should probably be rated as secondary range.

UFC10. Willow/ Kentucky bluegrass

(Salix spp./Poa pratensis)

n=2 This community type represents the grazed and disturbed community of the willow/ tufted hairgrass-sedge community type (UFB3). The high productivity and open nature of this community make it extremely attractive to domestic livestock. Heavy to moderate grazing pressure causes the native plant species to decrease and allows Kentucky bluegrass and dandelion to increase.

UFC11. Sedge-Slender wheatgrass-Rough fescue

(Carex spp.-Agropyron trachycaulum-Festuca scabrella)

n=29 This community type represents the grazed transects at the McCue Creek, Yara Creek and Upper James River rangeland reference areas over 30 years from the 1960's to the early 1980's. The continued grazing pressure since the 1980's has allowed Kentucky bluegrass to invade onto these sites to form a Kentucky bluegrass-Sedge dominated community type (Willoughby 2000). In the 1960's when these sites were protected from grazing the plant community succeeded back to a rough fescue-hairy wildrye dominated community.

UPPER FOOTHILLS SUBREGION

DECIDUOUS COMMUNITY TYPES

Figure 5. Aspen/Marsh reedgrass community type on south facing slopes in the Upper Foothills subregion

Deciduous community types

The six deciduous community types described in the Upper Foothills subregion are outlined in Table 4. Deciduous types are rare in this subregion. The cool climate severely restricts the growth of deciduous tree species (Strong and Leggat 1992). As a result, aspen and balsam poplar are generally found on south facing slopes where the increased insolation permits colonization.

The Pb-Sw/ Willow/ Yellow Mtn. avens community type (UFD2) is representative of the gravelly floodplains adjacent to rivers and streams. The Aw/ Rose/ Bearberry, Aw/ Rose/ Hairy wildrye and Aw/ Buffaloberry/ Hairy wildrye community types are found on dry south facing slopes throughout the region. The Aw/ Buffaloberry/ Hairy wildrye community type appears to be successionally more advanced, with slightly acidic soils, than the Aw/ Rose/ Hairy wildrye community type. The Aw/ Marsh reedgrass type is slightly moister than the other aspen community types found on south facing slopes in the Upper Foothills subregion and the Pb/ Willow/ Horsetail was described on the river floodplain adjacent to the Wildhay river.

Key to Deciduous Community Types

1. balsam poplar dominates the overstory. 2
   Drier sites with Aspen dominating the overstory 3

2. Low nutrient, dry gravelly river floodplains .. UFD2 Balsam poplar-White spruce/ Willow/ Yellow mtn. Avens
   Moist, moderately well drained soils ..... UFD6 Balsam poplar/ Willow/ horsetail

3. Dry , south and west facing slopes 4
   Moister richer sites with Marsh reedgrass dominated understory ..... UFD5 Aspen/ Marsh reedgrass

4. Bearberry or Buffaloberry dominate understory. 5
   Grass and forbs dominate the understory of this dry, sunny site ..... UFD3 Aspen/ Rose/ Hairy wildrye

5. Dry site conditions on steep south facing slope ..... UFD1 Aspen/ Rose/ Bearberry
   Lower, south facing slopes and lower nutrient soils (high pH) ..... UFD4 Aspen/ Buffaloberry/ Hairy wildrye

Table 4. Forage production (kg/ha) for the deciduous community types and ecosite phases within the Upper Foothills subregion

UFD1. Aspen/ Rose/ Bearberry

(Populus tremuloides/ Rosa acicularis/ Arctostaphylos uva-ursi)

n=1 This community type was described on the steep south facing slope above Rough Creek, west of Rocky Mountain House. The drier site conditions favour the growth of bearberry. This community type probably represents an earlier successional phase of the Pl/ bearberry community type described by Beckingham et al (1996). The forage productivity of this community type is only moderate, but the openness of the stand makes it accessible for livestock. This community type would be rated as secondary range.

UFD2. Balsam poplar/ Willow/ Yellow Mountain Avens

(Populus balsamifera/ Salix spp./ Dryas drummondii)

n=1 This community type is common throughout the Upper Foothills subregion on gravelly floodplains along rivers and streams. It is similar to the bearberry/ slender wheatgrass community (UFA10), but it is successionally more advanced. This type is dominated by balsam poplar with an understory of spruce in the later successional stages. This particular stand was fairly young with the tree canopy being less than 5 m tall. Yellow mountain avens is a common pioneer species on gravelly river bars and rocky slopes up into the alpine tundra (MacKinnon et al., 1992). As this community succeeds towards a mature forest, yellow mountain avens will undoubtably decline in cover.

The forage production on this community type is very low. The poor nutrient status of the soil limits the growth of grasses, forbs and shrubs. As a result, this community type would be rated as non-use range.

UFD3. Aspen/ Rose/ Hairy wildrye

(Populus tremuloides/ Rosa acicularis/ Elymus innovatus)

n=10 This community type is typical of aspen forest types found throughout the Upper Foothills subregion on south facing slopes. The dry site conditions and high solar insolation favours the growth of grasses and forbs rather than shrubs. The canopy cover of aspen is also noticeably lower on this community type. This community type is similar to the Aw/ buffaloberry/ hairy wildrye community (UFD4)described in Willmore Wilderness Park, but the absence of buffaloberry distinguishes this type from the Willmore type. This community is moderately productive for domestic livestock. This community would be rated as secondary range.

UFD4. Aspen/ Buffaloberry/ Hairy wildrye

(Populus tremuloides/ Shepherdia canadensis/ Elymus innovatus)

n=3 This community type was described along lower, south facing slopes and river terraces throughout Willmore Wilderness Park and areas west of Hinton. Bork (1994), found this community type. to be uncommon throughout Willmore, but pockets of this type were found along the Smoky, Sulphur and Sheep rivers on the North side of the Park. Bork felt that frequent disturbance and/ or arid conditions resulted in the aspen dominated overstory. He felt if left undisturbed, the community type would eventually succeed to a coniferous forest. This community type is very similar to the Aw/ buffaloberry type described by Youngblood (1993) in Alaska and the Aw/ rose/ hairy wildrye community type (UFD3) previously described near Rocky Mtn. House. The presence of buffaloberry distinguishes this northern type from the more southern rose type. The presence of buffaloberry may indicate a higher pH and lower nutrient status. Beckingham (1994), described Aw/ buffaloberry stands on lower pH sites.

This community type provides a good forage base for domestic livestock. In the Upper foothills, this community type is often located in close proximity to the trails and camps used by outfitters and recreationalists.

UFD5. Aspen/ Marsh reedgrass

(Populus tremuloides/ Calamagrostis canadensis)

n=4 This community type was described on a south facing slope in the Solomon valley west of Hinton and observed near Fall Creek and Upper James west of Rocky Mountain House. This community type is scattered throughout the valleys in small isolated areas. It appears to have a slightly higher moisture regime than the bearberry, hairy wildrye and buffaloberry dominated community types previously described. The dominance of marsh reedgrass indicates that some nutrient rich seepage occurs at some point in the growing season. This community type was located adjacent to Kentucky bluegrass-timothy dominated meadows (UFC8). As a result, this aspen dominated community type was extensively utilized by livestock.

UFD6. Balsam poplar/ Willow/ Horsetail

(Populus balsamifera/ Salix spp/ Equisetum arvense)

n=1 This community type was described on the flood plain of the Wildhay River northwest of Hinton. This community is not common in the Upper Foothills subregion and likely represents the continued succession of a willow/ horsetail dominated community type (UFB12). Continued succession in the absence of disturbance will likely lead to the development of a Sw/ horsetail dominated community type (UFE6).

This community type is being used by livestock because of its close proximity to a right of way that had been seeded to Creeping red fescue and clover. When in close proximity to primary range areas this community type should be rated as secondary range.

Conifer community types

Lodgepole pine dominates the overstory vegetation of the mesic reference sites in the Upper Foothills subregion. Typical forests are represented by the Pl/ bog cranberry (UFE1) and the Pl/ marsh reedgrass c.t. (UFE4) community types. Secondary succession is by white spruce and leads to the formation of the Pl-Sw/ bunchberry c.t. (UFE2). Continued succession on wetter sites, in the absence of disturbance, leads to a Sw/ horsetail/ moss dominated c.t. (UFE6) and to the Sw/ moss (UFE10) dominated community on more mesic sites.

Wetter, subhygric sites can be dominated by lodgepole pine, black spruce or white spruce. Many of these sites have a predominant willow understory (Pl/ willow/ moss (UFE3) or Sw/ willow(UFE7)). These types appear to represent continued succession from the native shrub and grassland community types. Succession in the absence of disturbance on these sites will be to white spruce. The Sw/ willow c.t. (UFE7) appears to be typical of a climax forest on these subhygric sites.

Black spruce dominates poorly drained depressional areas (Sb/ willow (UFE5)). These sites have a high water table throughout most of the year. Organic accumulations are a common result of the poor drainage conditions and low oxygen availability (Strong and Leggat, 1992).

Dry, south facing slopes are typically dominated by deciduous aspen forests with succession to a Sw/ bearberry (UFE8) and Pl/ bearberry/ hairy wildrye dominated community types (Beckingham et al., 1996). A Sw/ juniper (UFE9) c.t. was described on fine-textured, calcareous loess deposits, with high pH's near Brule lake. These deposits blow out of the Athabasca river valley from Jasper National Park.

The conifer forest types are generally unsuitable for livestock grazing and are typically rated as non-use. The ten coniferous community types described in the Upper Foothills subregion are outlined in Table 5. A more complete description of coniferous c.t. can be found in Beckingham et al. (1996).

Key to Coniferous Community Types

1. Lodgepole pine dominated community 2
   White or black spruce dominated community 5

2. The community is supported by well drained, coarse soil. It is often located on south facing slopes and exhibits a structured understory of grass, forb and shrub species 3
   The community is located on less developed, wet soils which support a willow understory ..... UFE3 Lodgepole pine/ Willow/ Moss

3. The community is succeeding to white spruce in undisturbed areas. Moss cover increases with canopy closure and grass, forb, and shrub species decline ..... UFE2 Lodgepole pine-White spruce/ Bunchberry
   The understory is dominated by shrubs, forbs or grasses 4

4. Shrubs dominate the understory on these well drained, south slopes ..... UFE1 Lodgepole pine/ Bog cranberry
   Forbs and grasses dominate the understory ..... UFE4 Lodgepole pine/ Marsh reedgrass

5. Dry site conditions 6
   Wet site conditions 7

6. Poor nutrient regime, bearberry dominates the understory, wind ..... UFE8 White spruce/ Bearberry
   Fine textured calcareous loess with a high pH ..... UFE9 White spruce/ Juniper-Buffaloberry

7. Drainage is poor, willow dominates the understory 8
   Mesic, moss dominates the understory 9

8. White spruce dominated overstory, wetter, low light ..... UFE7 White spruce/ Willow
   Black spruce dominated overstory, wet, often saturated soils ..... UFE5 Black spruce/ Willow

9. Wet soils, canopy is closing, promoting moss and loss of forb etc. ..... UFE6 White spruce/ Horsetail/ Moss
   Closed canopy, successionally mature ..... UFE10 White spruce/ Moss

UFE1. Lodgepole pine/ Bog cranberry

(Pinus contorta/ Vaccinium vitis-idaea)

n=8 This community type is common on dry, coarse textured, well drained sites throughout the Upper Foothills subregion and is part of the subxeric/ poor ecosite described by Beckingham et al. (1996). These sites are generally located on slopes with southerly aspects. This community type is very similar to the Pl/ hairy wildrye/ bunchberry community type described by Lane et al. (2000) in the Lower Foothills subregion, and the Pl-Sw/ low bush cranberry/ twinflower type described by Beckingham (1994) in the Upper Foothills subregion, but this community type appears to be drier with a poorer nutrient regime. Beckingham (1994), felt that white spruce would eventually dominate the canopy of this community type.

Generally, this community type is not useful for domestic livestock grazing because it does not produce good quality forage.

UFE2. Lodgepole pine-White spruce/ Bunchberry

(Pinus contorta-Picea glauca/ Cornus canadensis)

n=5 This community type represents the modal type on mesic/ mesotrophic sites throughout the Upper Foothills subregion and may be transitional to the Lower Foothills subregion if aspen occurs in the stand. Strong (1992), found that lodgepole pine dominated the reference sites in this subregion with white spruce succession occurring on undisturbed areas. Beckingham (1994), described a similar community type (Pl-Sw/ low bush cranberry/ twinflower) and felt that white spruce and balsam fir will eventually dominate the canopy. The change in canopy dominance will lead to a decline in understory cover of shrubs and forbs. As succession occurs, moss cover will increase.

This community type would be rated as non-use range for domestic livestock. There is little forage that

UFE3. Lodgepole pine/ Willow/ Moss

(Pinus contorta/ Salix spp./ Moss spp.)

n=3 This community type is very similar to the other lodgepole pine dominated community types, but it is found on wetter soils that lack development. This community type is slightly drier than the Pl-Sb/ labrador tea-whortleberry/ bunchberry/ feather moss type described by Beckingham (1994) and the Sb/ willow dominated community type (UFE5) described in this guide. Herbaceous plants are scarce in the understory of this community type. As a result, there is little forage for domestic livestock and this community would be rated non-use.

UFE4. Lodgepole pine/ Marsh reedgrass

(Pinus contorta/ Calamagrostis canadensis)

n=3 This community type is similar to the Pl /hairy wildrye/ fireweed-peavine community type described by Lane et al. (2000). The tree canopy is open which allows good understory growth.

The good understory forage production and easy access through this community type makes it useful for livestock grazing. If this community type occurs adjacent to a physical feature that attracts livestock to the area, it may be considered primary range.

UFE5. Black spruce/ Willow

(Picea mariana/ Salix spp.)

n=2 This community type is characterized by a dominant cover of black spruce and a sparse understory cover. The sites are moist in the spring and dry out later in the growing season. Corns and Annas (1986), found that these forests have a fire origin and can persist for more than 150 years.

This community type would be considered non-use for domestic livestock.

UFE6. White spruce/ Horsetail/ Moss

(Picea glauca/ Equisetum arvense/ Moss spp.)

n=3 This community type is successionally more advanced than the Pl-Sw/ bunchberry community type (UFE2) previously described. The lack of fire disturbance has allowed white spruce to succeed into the lodgepole pine canopy and dominate the site. As these stands mature, their canopies close, shading the understory vegetation and allowing moss cover to increase. The sparseness and low palatablity of the vegetation limits the use of these stands by domestic livestock.

UFE7. White spruce/ Willow

(Picea glauca/ Salix spp.)

n=1 This community type is similar to the Sw/ bunchberry/ moss community type, but is found on wetter sites, with poorer drainage. The wetter sites favour the growth of willow in the understory. The high cover of willow and spruce limits the amount of light reaching the understory. Consequently, there is little forage for domestic livestock.

UFE8. White spruce/ Bearberry

(Picea glauca/ Arctostaphylos uva-ursi)

n=1 This community type is similar to the Sw/ buffaloberry/ bearberry c.t. described by Lane et al. (2000) in the Lower Foothills. This type is fairly dry with a poor nutrient regime; as indicated by the high abundance of bearberry. It may also be somewhat windswept and desiccated, as indicated by the low tree canopy cover.

If this community type is located near a physical feature that attracts livestock to the area it may be considered to be primary or secondary range. In other instances though, where it is not near an attractive feature, this community type would be considered non-use.

UFE9. White spruce/ Juniper-Buffaloberry

(Picea glauca/ Juniperus horizontalis-Shepherdia canadensis)

n=2 This community type was described along the north shore of Brule lake. It is characteristic of the fine-textured, calcareous loess deposits which have blown down the Athabasca river valley from Jasper National Park. The soils of this community have a high pH (8) which supports a good cover of hairy wildrye. This community type is extremely slow growing. When harvested, the cutblocks resemble native grasslands (juniper/ hairy wildrye (UFF1) and rose/ hairy wildrye (UFF2)).

UFE10. White spruce/ Moss

(Picea glauca/ Moss spp.)

n=1 This community type represents a successionally mature forested stand in the Upper Foothills subregion. As succession occurs from pine to spruce, the canopy cover becomes closed and the amount of understory vegetation decreases until most of the shrub, forb and grass layers have been eliminated. As a result, there is limited forage available for domestic livestock within these spruce dominated community types. This community is typically rated as non-use for domestic livestock.

Cutblock and burn community types

In general, cutblocks provide only a limited source of forage for domestic livestock in the Upper Foothills subregion. The Brule stock association, Robb head tax permit and Upper James allotment are examples where the livestock rely principally on the forage within harvested cutblocks. On average, cutblocks produce twice as much forage as deciduous stands and nearly 3 times the forage as coniferous stands. In the Brule stock association, forage production on the cutblocks averaged 3-5 times greater than the unharvested white spruce dominated forest.

Two of the cutblock community types in this guide were described from the Brule stock association. These are the juniper/ hairy wildrye (UFF1) and rose/ hairy wildrye (UFF2) c.t.. Both of these types have very little growth of regenerating trees and resemble native grasslands (Figure 7).

Other cutblock community types were described on moister sites throughout the Solomon valley. These communities represent areas that were harvested 30-40 years ago. Currently, they are important sources of forage for domestic livestock throughout the area.

One burn community type was described from the Solomon valley. This burn occurred on an Se-Fa/ willow community approximately 10 years ago. The site was located in an area that had nutrient rich seepage that made it very productive for horses grazing the area.

In the Upper James and Wilson creek allotments west of Sundre, harvesting of lodgepole pine dominated sites produces fireweed/ hairy wildrye dominated communities on south and west facing slopes. On the more northern aspects in this area, the cutblocks tended to be dominated by moss to form the Pl-Sw/ moss community type. Livestock preferred to graze the fireweed/ hairy wildrye dominated cutblocks.

Figure 7. The juniper/ hairy wildrye community type (UFF1) results from the harvesting of a Sw/ juniper community.

UFF1. Juniper/ Hairy wildrye

(Juniperus horizontalis/ Elymus innovatus)

n=4 This community represents a harvested Sw/ juniper community along the north shore of Brule lake. It is characteristic of the fine-textured, calcareous loess deposits, which have blown down the Athabasca river valley from Jasper National Park. The soils of this community have a high pH (8) which supports a good cover of hairy wildrye. This community type is extremely slow growing. When harvested, the cutblocks resemble native grasslands.

This community is very similar to the rose/ hairy wildrye community, but appears to be in a later successional stage. This community type was described in older cutblocks (35 yrs) than the rose/ hairy wildrye community type (UFF2). As succession occurs on these cutblocks it appears that juniper and grass cover increase, causing a corresponding increase in forage production.

UFF2. Rose/ Hairy wildrye

(Rosa acicularis/ Elymus innovatus)

n=10 This community type represents a Sw/ juniper community that was harvested 20 years ago. It is very similar to the previously described juniper/ hairy wildrye community (UFF1), but lacks the cover of juniper. It appears that harvesting disturbance causes juniper to decline in cover. As succession occurs, juniper and grass density increase, causing forage productivity to increase. The site conditions are so harsh it appears that grass cover has to undergo succession onto the site.

UFF2a. Fireweed/ Hairy wildrye

(Epilobium angustifolium/ Elymus innovatus)

n=22 This community type represents a Pl/ moss community that was harvested 5-7 years ago. This community type was described on south and west facing slopes throughout the area. On more northerly aspects, moss dominates the understory of these cutblocks. Cutblocks can be an important source of forage for domestic livestock. They produce on average twice as much as deciduous stands, and nearly three times more than conifer stands. It must be remembered that this increase in forage is only temporary. As the cutblock undergoes succession there is a corresponding drop in production.

UFF3. White spruce/ Horsetail/ Kentucky bluegrass

(Picea glauca/ Equisetum arvense/ Poa pratensis)

n=1 This community type represents a Sw/ Horsetail community that was harvested 30-40 years ago along the banks of Moosehorn creek east of Rock Lake. These cutblocks are an important source of forage for domestic livestock and have been extensively utilized by cattle throughout the summer months. The high moisture and nutrient content of the sites make them extremely productive. Once invaded by agronomic species (Kentucky bluegrass and clover) they are extremely palatable to livestock.

UFF4. White spruce/ Moss

(Picea glauca/ Moss spp.)

n=1 This community type represents a Sw/ moss community that was harvested 30-40 years ago along the banks of West Solomon Creek. The regeneration on this cutblock is to subalpine fir which is similar to the understory of the Sw/ moss (UFE10) community that was harvested in the same area. This community is an important source of forage for wintering horses. The open canopy cover allows for a greater abundance of forbs and grasses in the understory. As the community continues to undergo succession and the canopy becomes denser there will be a corresponding drop in available forage.

PLANT COMPOSITION

	CANOPY COVER(%) MEAN	RANGE	CONST.
TREES			
WHITE SPRUCE *(Picea glauca)*	10	-	100

UFF5. River alder-Willow/ Fireweed-Cow parsnip

(Alnus tenuifolia-Salix spp./ Epilobium angustifolium-Heracleum lanatum)

n=1 This community type represents a Engelmann x White spruce-Subalpine fir community that was burned 10 years ago. The site was located within a nutrient rich seepage area, which favoured the growth of cow parsnip, fireweed and horsetail. The lack of tree canopy cover and moisture and nutrient regime of the area made the site very productive for domestic livestock. This site was extensively utilized by horses throughout the winter and summer months.

PLANT COMPOSITION	CANOPY COVER(%) MEAN	RANGE	CONST.

UFF6. Aspen/ Fireweed

(Populus tremuloides/ Epilobium angustifolium)

n=1 This community type represents a Pl-Sw/ bunchberry community that was harvested near the Robb area. The regeneration of this community back to aspen indicates that this particular cutblock is transitional to the Lower Foothills subregion. Indeed, the Robb area is on the border between the Upper and Lower Foothills subregions. This community type is highly productive for domestic livestock. Harvesting the trees allows the grasses and forbs to grow, increasing the forage productivity.

PLANT COMPOSITION	CANOPY COVER(%) MEAN	RANGE	CONST.

UFF7. Aspen/ Blueberry-Bearberry/ Hairy wildrye

(Populus tremuloides/ Vaccinium myrtilloides-Arctostaphylos uva-ursi/ Elymus innovatus)

n=2 This community type represents a Pl/ bog cranberry community (UFE1) that was harvested near the Robb area. The ecological conditions of this site are drier with a poorer nutrient regime. Regeneration of the trees will be much slower than the Aw/ fireweed community type which was described previously. Harvesting of the pine overstory allows grasses and forbs to flourish. This provides a good forage base for domestic livestock. Caution must be used when grazing cutblocks that the stocking rate is not too high to limit the growth of regenerating trees.

PLANT COMPOSITION

UFF8. Kentucky bluegrass-Creeping red fescue/ Clover

(Poa pratensis-Festuca rubra/ Trifolium spp.)

n=5 This community type represents cutblocks that have been heavily grazed by livestock. Heavy livestock grazing favours the growth of the invaders Kentucky bluegrass and timothy. The grazing pressure which favours the growth of these grass species is usually detrimental to the growth of trees. Cattle damage to the conifer trees is usually trampling damage which scars the trees and breaks the stem.
